By TOM ZELLER

The grand physical imprint of a disaster is often a fleeting thing. Shattered glass is swept, gaping black holes mended, snarls of steel and mortar raked. But subtle and perhaps more harrowing inscriptions remain, including one that was quietly etched into existence some 25 miles from lower Manhattan and the terrorist attacks that toppled two skyscrapers.

Columbia University's Lamont-Doherty Earth Observatory in Palisades, N.Y., has been monitoring seismic activity in the northeastern United States since the early 1970's, and at 8:46 a.m. last Tuesday, its needle wiggled. Eighteen minutes later, another twitch. A third — this one a bit stronger, more sustained — followed at 9:59 a.m. And precisely 29 minutes after that, a final pulse.

Then it was over.

"In this field, we often have to look at seismograms and know that these waves represent the deaths of a lot of people," said John Armbruster, a scientist at the observatory. "The sad thing is that usually we're dealing with a natural event like an earthquake."

The series of tremors generated by the unfolding attacks at the World Trade Center were relatively small. The final collapse delivered a mild Richter blow not unlike the mini-quake some New Yorkers might have felt earlier this year — a mere bump, in seismic terms. And both events scratched fairly low-ranking, albeit lasting testaments to the speed, amplitude and duration of their rumbling.

But the quake's reading, for all of its dramatic peaks and valleys, is really little more than a mindless scribble — dumb, unknowing, without purpose. The tower's imprint, on the other hand — less rapid and not as deep — seems a sad, sinister tracing of intent and tragedy.

"An earthquake is something that gets out of the earth and into a building," Mr. Armbruster said. "But this event began with a building, was caused by human activity, and a subsequent effect leaked into the earth."

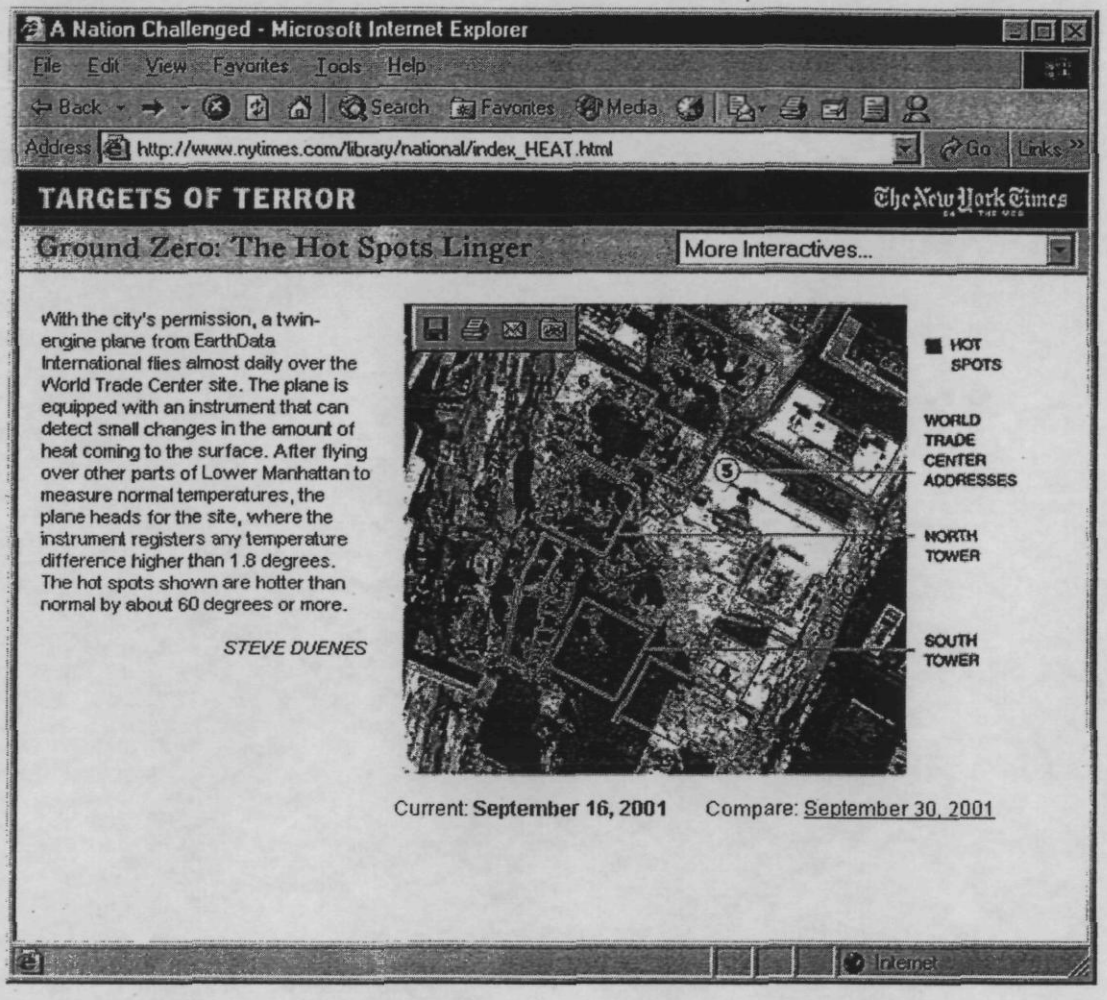
hot spots linger



With the city's permission, a twin-engine plane from EarthData International flies almost daily over the World Trade Center site. The plane is equipped with an instrument that can detect small changes in the amount of heat coming to the surface. After flying over other parts of Lower Manhattan to measure normal temperatures, the plane heads for the site, where the instrument registers any temperature difference higher than 1.8 degrees. The hot spots shown are hotter than normal by about 60 degrees or more.
